

# Remoteprint

If you wish to use printing solutions that you don't have in-house, the Remoteprint module might be the answer

## Effective

Outsource document printing and save time

## Economic

Outsourcing large-volume printing can be cost efficient

## Remoteprint

The module lets you send a print-data file to a remote print-shop where the data is read and associated with the templates stored at the remote location.

It is important that the templates used locally (the copy saved in the document archive) and the templates stored at the remote print-shop are the same. Differences in the templates will lead to differences in the original letter, sent to the receiver, and the copy, stored in the document archive.

Remoteprint lets you create a data-file, containing letter data, in a folder that you choose in the System Setup in Predator CMS. The data-file must be transferred (manually) to the chosen print-shop for processing.

The file is created as a .txt-file with special ASCII print characters for field separation. When the data file is created, a PDF-copy for the local document archive is made. The PDF uses the local lettertemplate and the printed original uses the lettertemplate kept at the print-shop.
